# HellBurn's Vault

NFT-Powered Deflationary Burn Vault

Whitepaper v1.0

Built on HellBurn Protocol — Ethereum Mainnet

## 1. Introduction

HellBurn's Vault is a new DeFi protocol built on the HellBurn ecosystem on Ethereum Mainnet. It combines three powerful concepts: NFT ownership, automatic ETH yield generation, and deflationary burn mechanics.

The core idea is straightforward: you mint an NFT with ETH, the Vault automatically deploys that ETH across three yield-generating strategies, and you receive a proportional share of the generated ETH — passively, forever, as long as you hold your NFT.

HellBurn's Vault is fully trustless — no admin key, no pause function, no withdrawal mechanism. Like HellBurn Protocol itself, it is immutable once deployed.

## 2. The Problem

Most DeFi protocols share the same fundamental challenges:

- Too complex for regular users — multiple tokens, multiple steps, manual management
- Passive income requires active participation — staking, claiming, compounding
- No real deflationary pressure — token supply grows, value dilutes
- No external capital inflow — protocols recycle existing capital

**HellBurn's Vault solves all four problems in a single product.**

## 3. The Solution — HellBurn's Vault

HellBurn's Vault is an NFT-gated deflationary burn vault:

- One action only: mint an NFT with ETH — everything else is automatic
- Three yield sources: burn deflation + LP trading fees + ETH staking
- Fully passive: ETH rewards flow to NFT holders automatically

- Deflationary: every mint permanently reduces HBURN supply
- Trustless: no admin, no pause, no withdrawal keys — ever
- Limited supply: maximum 10,000 NFTs total across all tiers

### How It Works — Step by Step

| | |
|---|---|
| 1 | User chooses a tier and mints an NFT by sending ETH to the Vault |
| 2 | 50% of ETH immediately buys HBURN on open market and burns it permanently to 0x000...dEaD |
| 3 | 40% of ETH is deployed into HBURN/ETH Uniswap V3 Concentrated Liquidity pool |
| 4 | 10% of ETH is staked via Lido — generating ~4% APY in stETH yield |
| 5 | Any permissionless caller can trigger LP rebalancing when price drifts outside the range |
| 6 | All yield (LP fees + stETH rewards) is continuously collected by the Vault |
| 7 | 80% of collected yield is distributed to NFT holders proportional to tier multiplier |
| 8 | 20% of collected yield re-enters BuyAndBurn — buying and burning more HBURN |
| 9 | NFT holders receive ETH passively — no staking, no claiming strategies, no manual steps |

## 4. NFT Tier System

HellBurn's Vault offers four NFT tiers. Each tier has a fixed ETH mint price, limited maximum supply, and a reward multiplier. The multiplier is designed to be proportional to the mint price with a moderate bonus for higher commitment — ensuring fairness while incentivising larger participation. Maximum 5 NFTs per tier per wallet prevents single-wallet dominance.

| Tier | Mint Price | Max Supply | Max/Wallet | Multiplier | Max Pool |
|---|---|---|---|---|---|
| 🥉 **Bronze** | 0.1 ETH | 5,000 | 5 | **1x** | 500 ETH |
| 🥈 **Silver** | 0.5 ETH | 3,000 | 5 | **5x** | 1,500 ETH |
| 🥇 **Gold** | 1.0 ETH | 1,500 | 5 | **9x** | 1,500 ETH |
| 💎 **Diamond** | 5.0 ETH | 500 | 5 | **40x** | 2,500 ETH |
| **Total** | | 10,000 | | | 6,000 ETH |

**Total maximum vault capacity: 6,000 ETH. Once all NFTs of a tier are minted, that tier is permanently closed — no exceptions.**

# 5. Tokenomics & ETH Flow

## Mint ETH Allocation

When a user mints an NFT, the ETH is immediately deployed:

| Allocation | Destination | Purpose |
|---|---|---|
| **50%** | Buys & burns HBURN permanently | Maximum deflationary pressure on HBURN supply |
| **40%** | HBURN/ETH Uniswap V3 Concentrated LP | Generates trading fee yield — managed by permissionless rebalancer |
| **10%** | Lido Liquid Staking (stETH) | Generates ~4% APY ETH staking yield |

## Yield Distribution

All generated yield is distributed as follows:

| Share | Recipient | Effect |
|---|---|---|
| **80%** | NFT Holders | Proportional to tier multiplier — paid in ETH |
| **20%** | BuyAndBurn | Buys & burns more HBURN — compounds deflation |

## The Deflationary Loop

| | |
|---|---|
| **1** | More NFT mints → more ETH into the Vault |
| **2** | More ETH → more HBURN bought from open market (buy pressure) |
| **3** | More HBURN burned → total supply decreases permanently |
| **4** | Lower supply → higher HBURN price per token |
| **5** | Higher HBURN price → more valuable LP position → more trading fees |
| **6** | More trading fees + stETH yield → more ETH for NFT holders |
| **7** | Higher ETH yield → more attractive for new minters |
| **8** | Cycle compounds — stronger with every new participant |

# 6. Trustless LP Management

The 40% LP allocation uses Uniswap V3 Concentrated Liquidity within a defined price range around the current HBURN/ETH market price. Concentrated Liquidity significantly increases capital efficiency and trading fee yield compared to standard full-range LP positions.

### Permissionless Rebalancing

When the HBURN price moves outside the defined LP range, the position stops earning fees. To address this without any admin access, HellBurn's Vault implements a permissionless rebalancer — a public function that anyone can call to trigger a range adjustment.

This is the same trustless pattern used in HellBurn Protocol for finalizeEpoch() — anyone can trigger it, no one controls it. Callers may receive a small ETH incentive from the Vault to cover gas costs.

> ⚠ *Impermanent Loss Notice: Concentrated Liquidity LP positions carry impermanent loss risk when the price moves significantly outside the defined range before rebalancing occurs. The tight range strategy and permissionless rebalancing mechanism are designed to minimise this risk, but it cannot be eliminated entirely. See Section 9 (Risk Disclosure) for full details.*

## 7. Break-Even & Return Projection

The table below illustrates estimated break-even timelines based on a conservative 12% annual ETH yield assumption (combining LP fees and stETH staking). Actual yield will vary depending on HBURN trading volume, LP fee tier, and stETH APY at time of participation.

| Tier | Mint | Est. Annual Yield* | Break-Even | NFT Value at Break-Even |
|---|---|---|---|---|
| 🥉 **Bronze** | 0.1 ETH | ~0.012 ETH (12%) | ~8.5 years | Appreciating |
| 🥈 **Silver** | 0.5 ETH | ~0.060 ETH (12%) | ~8.5 years | Appreciating |
| 🥇 **Gold** | 1.0 ETH | ~0.120 ETH (12%) | ~8.5 years | Appreciating |
| 💎 **Diamond** | 5.0 ETH | ~0.600 ETH (12%) | ~8.5 years | Appreciating |

** 12% APY is a conservative estimate. Higher HBURN trading volume will increase LP fees significantly above this baseline. NFT resale value is not included in this calculation — a Diamond NFT generating 0.6 ETH/year will appreciate in secondary market value as yield grows.*

**Important: The NFT itself retains and likely appreciates in value. Early minters benefit most — same tier, same mint price, but growing yield as more ETH enters the Vault and HBURN supply decreases.**

## 8. Risk Disclosure

HellBurn's Vault is designed to minimise risk through trustless architecture and diversified yield sources. The following table provides a transparent overview of known risks and the mitigations in place:

| Risk | Severity | Mitigation |
|---|---|---|
| **Impermanent Loss (LP)** | Medium | Concentrated Liquidity with tight range + permissionless rebalancer minimises IL significantly |
| **Lido smart contract risk** | Low | 10% allocation only — limited exposure; Lido is battle-tested with $30B+ TVL |
| **HBURN price volatility** | Medium | Vault ETH is deployed at mint — not dependent on HBURN price for yield generation |
| **Low trading volume** | Medium | LP fees depend on HBURN trading volume — more adoption = more yield |
| **All NFTs minted out** | Low | Yield continues from LP fees + staking; secondary market ensures price discovery |

## 9. Security & Trustlessness

HellBurn's Vault follows Trustless v4.0 principles — identical to HellBurn Protocol:

- No admin key — parameters cannot be modified after deployment
- No pause function — the protocol cannot be stopped by any party
- No withdrawal function — ETH and assets in the Vault are non-extractable
- Permissionless LP rebalancer — anyone can trigger, no one controls
- Max 5 NFTs per tier per wallet — prevents single-wallet dominance
- SpyWolf Security audit before mainnet deployment
- Full source code verified on Etherscan

## 10. NFT Transferability & Secondary Market

- HellBurn's Vault NFTs are fully transferable ERC-721 tokens
- Selling transfers all future ETH yield rights to the buyer
- As HBURN supply decreases and yield grows, NFT floor prices should appreciate
- Early minters benefit most — same tier, same price, but growing yield over time
- Diamond NFTs (only 500 exist globally) are expected to become the most sought-after

## 11. Roadmap

| Phase | Milestone |
|---|---|
| **Phase 1** | Smart contract design & architecture |
| **Phase 2** | Internal testing & SpyWolf security audit |
| **Phase 3** | Testnet deployment & community beta |
| **Phase 4** | Mainnet launch — NFT minting opens |

| Phase | Milestone |
|---|---|
| **Phase 5** | Secondary NFT market & DexScreener listing |
| **Phase 6** | Ecosystem integrations & partnerships |

## 12. Disclaimer

This whitepaper is for informational purposes only and does not constitute financial advice. DeFi protocols carry inherent risks including smart contract vulnerabilities, market volatility, impermanent loss, and liquidity risks. The estimated 12% APY and break-even projections are illustrative only and are not guaranteed. The ~4% APY referenced for Lido staking is an approximation based on current market conditions and may vary. Always conduct your own research (DYOR) before participating in any DeFi protocol. Past performance is not indicative of future results. This document is a draft and subject to change based on community feedback and technical development.
